Providing lab results requires everyone’s cooperation. The process of drawing the blood is the most crucial step to obtaining accurate results. Thank you for all of your hard work and dedication to providing the best care possible for our patients.

**HOW DO THESE PROBLEMS AFFECT TEST RESULTS?**

- **Hemolysis** - Falsely increased potassium (K), Magnesium (Mg), Phosphate, D-Dimer is affected unpredictably
- **Clotted** - Falsely decreased platelets (plt) and hemoglobin (Hgb), and the PT and PTT can be either falsely increased or decreased depending on the size and composition of the clot
- **IV Contamination** - Affects many analytes due to a dilution effect and contamination of the fluids/medications. Examples include falsely low Hgb, plt, and WBC count, falsely increased sodium (Na), Chloride (Cl), and PT/PTT
- **EDTA Contamination in a Chemistry tube** - Falsely increased K and falsely decreased Calcium (Ca)
- **Delayed turnaround time** - Recollecting the sample adds time
- **Prolonged tourniquet time** - Possible hematoma formation and erroneously high values for all protein based analytes, Hgb, and other cellular elements. **Do not exceed 1 minute**
- **Patient ID Errors** - Potential for serious injury to the patient if clinical decisions or blood products given based on mislabeled specimens
HEMOLYZED SPECIMENS

Hemolysis is caused when red blood cells (RBCs) are destroyed and hemoglobin is released into the plasma or serum. Hemolysis can be seen after the blood sample is spun down in a centrifuge. The plasma or serum will be pink (slight hemolysis) to red (gross hemolysis).

### Patient Conditions that May Cause Hemolysis
- Hemolytic anemia
- Liver disease
- Transfusion reactions

### Procedural Causes of Hemolysis
- Collecting blood when starting an IV
- Using a needle with a bore too small for the vein
- Using too large of a tube when using a small-diameter butterfly needle
- Drawing blood from a vein that has a hematoma
- Continuing sluggish draws caused by collapsed veins or improper needle placement
- Excessive squeezing of the site when obtaining a skin puncture specimen
- Mixing the tubes too vigorously or rough handling during transport
- Frothing of the blood caused by improper fit of the needle on a syringe
- Excessive force on the syringe plunger
  - keep < 1 mL dead space
- Forcing the blood from a syringe into an evacuated tube

### UNDERFILLED/OVERFILLED TUBES
- Most tubes have additives to prevent clotting or stabilize analytes when the correct amount of blood is added.
- Each test also requires a minimum volume of blood for pipetting and follow-up testing.
- Underfilled/overfilled tubes can lead to erroneous lab results for some tests.
- Results can be falsely reduced by dilution if underfilled or the specimen may clot if overfilled due to insufficient anticoagulant.
- The light blue sodium citrate tube for coagulation testing must be filled to the line.
  - There is a crucial 9:1 ratio of blood to anticoagulant.
  - If the ratio is disturbed by either too little or too much blood (the tube is filled up to the cap) the lab results will be inaccurate.
- It is also very important to draw a discard tube before collecting a sodium citrate tube because of tissue thromboplastin (a clotting factor that is activated when the skin is pierced).
  - If using a butterfly, a discard tube ensures the tube will fill properly by getting rid of the air in the tubing.

### CLOTTED SPECIMENS
Lack of or inadequate mixing of tubes is the major cause of clot formation. To help stop the specimen from clotting, mix the tube by gently inverting it a minimum of 3 times immediately after filling it with blood. Then continue to gently invert the tubes a total of 8 times to completely mix. Line draws into a syringe must be transferred by piercing the vacutainer cap without delay and gently mixed to avoid clotting.
IMPROPERLY COLLECTED OR PATIENT ID ERRORS

Correct identification of patient specimens using 2 patient identifiers is essential for reporting accurate laboratory results. Documenting specimen collection via scanning and proper label placement is critical to safe, accurate, and timely lab completion. Follow the steps outlined in the IHIS specimen collection tip sheets with the following key takeaways:

- Always Scan Before you Move to complete the collection documentation, including clicking [Accept]
- Always document the source for specimens other than blood including specimen type and collection site

A variety of blood collection tubes and urine preservatives are necessary to maintain specimen stability until testing can be performed in the laboratory. Refer to the Lab Testing Menu on OneSource or the lab test label for acceptable tube types.
